ROULING AND PROORD SHEET

INSTRUCTIONS: Officer designations should be used to the "TO" op this incomment a line should be return stores there are each comment numerical to concerned with the comment for "TO" to turn. Each officer should be falled to see a subject of the store under comment numerical to concern Seed should be not income and record Seed should be not under a Rective.

What animal tests or observations would be significant in a study of phychogonic materials? To what extent and in what wanner do you feel animal data would correlate with elimical observations on humans?

What special characteristics of mescaline, Rauwolfia, and LSD respectively, lead you to feel they may be of value when used in combinations? In what way would you expect the characteristics of one to complement, antagonize, or accentuate the characteristics of another, and how would this be of value?

In what way would you expect a combination of chlorpromuzine and corpacil to be superior to one or the other alone?

In what specific ways and to what extent do you feel "maggestion" may influence the effects observed and reported in Individuals who have taken materials such as LEO, rescaling, etc? In other words, how may the subject's expectations, the investigator's expressed or implied expectations, attitude, etc., influence the observed effects of such materials? If such factors can be expected to influence the observed effects, in what way can a person take this into consideration in the evaluation of investigations with LEO, mescaling, etc?

To what extent do you feel the above factors may influence the results of clinical evaluations of drugs which are now ordinarily considered psychogenic, and how may these effects to evaluated? The statement is often made that FW statutes with either surface or deep electrodes would be very useful in testing psychogenic drugs. Considering the present knowledge of the art, do you feel that it would be possible:

- (a) To establish a reproductible show-contextic pattern of cortical (or sub-cortical) electrical activity in human beings referable to a given does of psychogenic material when that does is in the sermal effective does range?
- (b) To relate such patterns of electrical activity to observable alterations in affect or behavior such as the production of supporta, dependentiation, subtle changes in the level of application, els?

It often appears that a known combination of environmental factors and/or the administration of certain materials produce in human beings an alteration of state such that the materials or environmental situations are characterized by the observer as "psychogenic". The problem which inevitably arises from this observation is that of defining the limits of the personality alteration in terms of behavior in such a way as to make possible an assessment of the reality and unsfulness of the observed effects in otherwise "normal" subjects.

In such a situation as that outlined above can you suggest tests which would evaluate objectively changes in such factors as strength of motivation, capacity for critical judgment, ability to relate to others, memory, versatility in role playing generativity to changes in impediate environment, changes in level of aspiration or their correlates produced in an individual by much treatment?
